

International Observe the Moon Night 2024

LUNAR MARIA (SEAS) • SOUTHERN HEMISPHERE • SATURDAY, SEPTEMBER 14

Moon Map

This map depicts the Moon as it will appear from the southern hemisphere on International Observe the Moon Night, September 14, 2024, at 19:00 in Mexico City and 20:00 in Lima (00:00 UTC September 15).

Lunar Maria (Seas)

Once thought to be seas of water, these are actually large, flat plains of solidified basaltic lava. They can be viewed in binoculars or even with the unaided eye. Some of the maria are circular, hinting at origins from giant asteroid impacts that created great basins, which were later flooded with lava. Other maria are irregular and have more mysterious origins. Tonight you may be able to identify 16 maria on the near side of the Moon.

INTERNATIONAL OBSERVE THE MOON NIGHT 2024 • LUNAR MARIA (SEAS) • SOUTHERN HEMISPHERE

A. Mare Frigoris
(Sea of Cold)

B. Mare Imbrium
(Sea of Rains)

C. Mare Insularum
(Sea of Isles)

D. Oceanus Procellarum
(Sea of Storms)

E. Mare Cognitum
(Known Sea)

F. Mare Humorum
(Sea of Moisture)

G. Mare Nubium
(Sea of Clouds)

H. Mare Vaporum
(Sea of Vapors)

I. Mare Serenitatis
(Sea of Serenity)

J. Mare Tranquillitatis
(Sea of Tranquility)

K. Mare Nectaris
(Sea of Nectar)

L. Mare Fecunditatis
(Sea of Fertility)

M. Mare Crisium
(Sea of Crises)

N. Mare Anguis
(Serpent Sea)

O. Mare Undarum
(Sea of Waves)

P. Mare Spumans
(Sea of Foam)

These charts show the positions and extents of the 16 lunar seas visible on the Moon tonight, with south up and lunar west to the right. You may be able to find the larger seas without any special equipment. Smaller seas may be challenging to find even through binoculars. Combine these charts with the accompanying map and see how many of the Moon's maria you can track down tonight!

International Observe the Moon Night 2024

HUMAN LANDING SITES • SOUTHERN HEMISPHERE • SATURDAY, SEPTEMBER 14

Moon Map

This map depicts the Moon as it will appear from the southern hemisphere on International Observe the Moon Night, September 14, 2024, at 19:00 in Mexico City and 20:00 in Lima (00:00 UTC September 15).

This map is designed for use on September 14, 2024, but can be used on nearby dates or anytime the Moon is at or near the same phase.

Lunar Landing Sites

Between July 1969 and December 1972 a total of 12 astronauts landed on the surface of the Moon for six of the Apollo missions. Apollo missions 11, 12, 14, 15, 16, and 17 each landed in different locations on the lunar surface. These locations, each fascinating for their own particular reasons, sampled a wide range of lunar geology and terrain, from smooth mare plains to rugged ancient highlands. All six landing sites are visible tonight. Use this map and the magnified charts on the other side of this sheet to find and observe these historic sites.

Map generated with NASA's Dial-A-Moon
(<https://svs.gsfc.nasa.gov/5187>)

Apollo 11

The first human landing site was on the smooth flat plains of the Sea of Tranquility. Despite how flat the area looks from Earth and from lunar orbit, astronauts Neil Armstrong and Edwin "Buzz" Aldrin had to maneuver their lander at the last minutes of their descent in order to avoid a field of giant boulders.

Apollo 12

In November 1969, a pinpoint landing brought astronauts Charles "Pete" Conrad and Alan Bean down next to the robotic Surveyor 3 spacecraft, which had landed there in April 1967. The astronauts collected samples of material blasted from the formation of Copernicus crater over 350 km away and 800 million years ago.

Apollo 14

Astronauts Alan Shepard and Edgar Mitchell landed in a broad expanse of low, rolling hills in February 1971. Rock samples returned by the mission told the story of how this landscape was formed nearly 4 billion years ago by debris blasted from the formation of the basin now occupied by Mare Imbrium.

Apollo 15

In July 1971, astronauts David Scott and James Irwin landed at the edge of Mare Imbrium at the base of the towering Apennine Mountains. Driving their rover across the mare and up the lower mountain slope, they gathered samples from the dark plains and the surrounding, light-colored lunar highlands.

Apollo 16

This was the first and only mission to land in the rugged lunar highlands. In April 1972, astronauts John Young and Charles Duke collected rock samples more than 4 billion years old. These showed that the ancient lunar crust formed from rock that crystalized and floated to the top of a global lunar magma ocean.

Apollo 17

The final Apollo mission to land on the Moon visited the spectacular Taurus-Littrow Valley, deeper than Earth's Grand Canyon. In December 1972, astronauts Eugene Cernan and Harrison "Jack" Schmitt (the first professional geologist on the Moon) explored an active fault scarp, a gigantic landslide deposit, and brought back samples that included beads of volcanic glass erupted in an ancient lunar fire fountain.

International Observe the Moon Night 2024

SELECTED OBJECTS FOR TELESCOPIC VIEWING • SOUTHERN HEMISPHERE • SATURDAY, SEPTEMBER 14

Moon Map

This map depicts the Moon as it will appear from the southern hemisphere on International Observe the Moon Night, September 14, 2024, at 19:00 in Mexico City and 20:00 in Lima (00:00 UTC September 15).

Many of the best views will occur along the terminator (the line between the day and night side of the Moon).

This map is designed for use on September 14, 2024, but can be used on nearby dates or anytime the Moon is at or near the same phase.

Selected Telescopic Objects

Some of the more interesting lunar landforms that have favorable lighting for viewing tonight are identified here. Details for each are on the reverse side of this map.

Map generated with NASA's Dial-A-Moon
(<https://svs.gsfc.nasa.gov/5187>)

- 1 Gruithuisen Domes
- 2 Aristarchus Plateau
- 3 Marius Hills
- 4 Gassendi Crater
- 5 Schiller Crater
- 6 Tycho Crater

1. Gruithuisen Domes

These very unusual volcanoes were formed by thicker lava than is typical on the Moon. As a result, they stand taller (1,800 m) and are steeper than average lunar volcanoes. Two large domes are most easily visible. Mons Gruithuisen Delta lies to the east (right in this view) of Mons Gruithuisen Gamma. A third, smaller volcano, Mons Gruithuisen NW, lies to the northwest (upper left in this view) of Mons Gruithuisen Gamma.

2. The Aristarchus Plateau

This region is a geologic wonderland on the Moon! Aristarchus Crater (40 km diameter) is a relatively deep, young, and fresh impact crater with beautifully terraced walls and a sharp central peak. Herodotus, to the west, has a slightly smaller diameter, but is older and partially flooded by lava. North of both is the blocky, volcanic Aristarchus Plateau, blanketed in dark volcanic ash. Cutting through the plateau is Schröter's Valley, one of the most spectacular examples of a sinuous rille, a 160 km channel cut by flowing lava.

3. Marius Hills

To the north and west of the crater Marius lie a few hundred volcanic cones and domes: the Marius Hills. Smaller than the volcanoes of the Gruithuisen Domes, they are still composed of lava that was thicker than typical lunar lava. They are notoriously difficult to observe unless the local sunlight is streaming across them nearly horizontally. Fortunately, that will be the case on International Observe the Moon Night 2024! We'll get to watch a lunar sunrise across this knobby terrain.

4. Gassendi Crater

Gassendi has been called one of the Moon's most beautiful impact craters. It has a large 110 km diameter but a shallow 2.8 km depth. Gassendi is a fine example of a floor-fractured crater. Magma welled up beneath Gassendi and pushed its floor and cluster of central peaks up like a piston. A network of cracks formed on the floor as it rose. This object is a challenge for lunar observers.

5. Schiller Crater

Near the Moon's limb or visible edge, all craters look like ovals due to viewing geometry. But Schiller is a particularly extreme example. That is because Schiller actually is an oval, measuring 179 x 71 km, making it the least circular large crater on the Moon. Its origin remains a mystery. Was it formed by a single large impactor coming in at a very low angle, or by multiple overlapping impacts? All current proposed explanations have problems. Look closely and see what you think.

6. Tycho Crater

Measuring 85 km across, Tycho is a spectacular example of a complex impact crater. It has a sharp, towering central peak rising from a deep, flat floor. The inner faces of the crater's rim are broken into series of terraces stepping down to the crater floor. Tycho's details are so sharp and well defined because it is young and fresh, estimated at only 108 million years old. That's young for a lunar crater! Surrounding the crater is a pattern of scoured scars and bright rays of pulverized rock ejected by the impact.
